54

The use of a specific tumor associated antigen, sialosyllactotetraose, in diagnostic or therapeutic procedures related to cancer diseases.

57

This invention relates to the use of a specific tumor associated antigen of carbohydrate nature, sialosyllactotetraose-(IV³NeuAcLcOse₄) for diagnostic and therapeutic procedures related to human tumor diseases.

EP 0 173 663 A2

THE USE OF A SPECIFIC TUMOR ASSOCIATED ANTIGEN,
SIALOSYLLACTOTETRAOSE, IN DIAGNOSTIC OR THERAPEUTIC
PROCEDURES RELATED TO CANCER DISEASES.

Field of the invention

This invention relates to the use of a specific tumor associated antigen of carbohydrate nature, sialosyllactotetraose-IV³NeuAcLcOse₄-(IUPAC-IUB Lipid Document, 1977) for diagnostic and therapeutic procedures related to human tumor diseases.

Background

It is established that the transformation of tissue cells to tumor cells is associated with a change of the carbohydrate structure on the cell surface. Many carbohydrate structures serve as antigens and the tumor-modified structures represent a type of so-called tumor-associated antigens. The cell surface carbohydrate structures are linked either to a lipid moiety, in which case they are called glycolipids, or to proteins (peptides), in which case they are called glycoproteins (glycopeptides). A common designation for the two forms is glycoconjugate.

Tumor-associated glycoconjugate antigens are previously known in relation to human tumor diseases. In melanomas the carbohydrate structures sialosylganglioside and sialosyllactose have been identified linked to a lipid portion. Two carcinoma associated antigens CEA (carcino-embryonal antigen) and GICA (gastrointestinal cancer antigen) have been demonstrated particularly in gastrointestinal carcinomas while a third antigen, CA-50, seems to be a general carcinoma antigen. All these antigens are secreted from the tumor cell surface and can be demonstrated in blood serum.

0173663

The present invention is based on the surprising discovery that patients with many forms of carcinoma express in the primary tumor and its metastases a glycoconjugate, which is not expressed in normal tissue.

5

In accordance with the invention the glycoconjugate antigen has been isolated as a glycolipid antigen. It is a ganglioside having the complete chemical structure NeuAc α -3Gal β -3GlcNAc β -3Gal β -4Glc-Cer or NeuAc LcOse₄Cer (IUPAC-IUB Lipid Document, 1977). A glycolipid having the basic structure of the present ganglioside but with no sialic acid has been demonstrated in i.a. human meconium but in spite of extensive investigations it has not been possible to demonstrate the present ganglioside in any human tissue from an adult. However, it has been possible to find said ganglioside in lipid extracts in many carcinomas in different organs. Within the scope of the present invention sensitive procedures have been elaborated for the detection of said antigen in body fluids and tissues. All the procedures are based on the fact that the antigen which is present in very low concentrations is determined by binding to a specific monoclonal antibody. Several monoclonal antibodies have been prepared upon immunization of mice with a human colon carcinoma cell line. Said monoclonal antibodies define sialosyllactotetraose when it is present as a monosialo ganglioside, i.e. a carbohydrate - containing lipid which contains a sialic acid as a characteristic component but it also defines all those antigens where the same carbohydrate structure is bonded to a protein. The sialic acid is necessary for the antigen activity since hydrolysis of the antigen with sialidase enzyme completely removes the ability of the antigen to bind to the monoclonal antibodies. The monoclonal antibodies also define antigens which, in addition to sialosyllactotetraose, contain a fucose moiety linked to the molecule.

25

30

35

0173663

Within the scope of the present invention procedures have been elaborated for the isolation of the tumor associated glycolipid, sialosyllactotetraosylceramide, in pure form from human tumor tissue. The purified ganglioside has by a special process obtained an increased immunogenic activity and has been used for the production of monoclonal antibodies. Procedures have, within the scope of the invention, been developed for the identification and determination of said antigen in tissues, tissue sections, and body fluids. All of these methods for diagnostic purposes are based on the fact that the antigen can be detected by binding to the specific monoclonal antibodies produced against the pure ganglioside antigen, sialosyllactotetraosylceramid. The following examples illustrate the various sources where the ganglioside antigen can be measured: surgical or autopsy material of tumor tissue from lung, liver, intestine, stomach or pancreas as well as cells obtained by biopsy of tumor tissue in different organs, by aspirations of the stomach or respiratory tract, expectorations, or by puncture of pleural or abdominal cavity, and biological fluids like blood, blood plasma, serum, lymph fluid, cerebrospinal fluid, urine, saliva or similar.

The antigen which is used according to the present invention is termed, sialosyllactotetraose and has the following structure: $\text{NeuAc}\alpha\text{-3Gal}\beta\text{-3Glc-NAc}\beta\text{-3Gal}\beta\text{-4Glc}$ or $\text{IV}^3\text{NeuAcLcOse}_4$ (IUPAC-IUB Lipid Document, 1977). Within the scope of the present invention all antigens fall, which have been modified by linking fucose to the N-acetylglucosamine molecule in a $\alpha\text{-4}$ bond. The antigens used to define the monoclonal antibodies have been produced from antigens bound to a lipid group but also includes the binding to every other compound.

The antigen used according to the invention can be isolated from tumor tissue, obtained by autopsy of patients. A

0173663

particularly good source are certain forms of lung carcinoma. The concentration of the antigen in the tumor tissue is in general low, and the isolation of the antigen will then be laborious. We have found another biological starting material for the isolation of the tumor antigen.

The cell line Colo 205 results in tumors when implanted to so-called nude mice (generic name nu/nu). These tumors contain a high concentration of the antigen to which also fucose is linked. By treating the isolated ganglioside with the α -fucosidase enzyme the fucose moiety may be split off and the glycolipid antigen be obtained in pure form.

The present invention concerns in accordance herewith the induction of the tumor antigen with chromatographic methods from tumors induced by Colo 205 cells on so-called nude mice or from human tumors. The present invention also relates to the production of monoclonal antibodies against the purified antigen adsorbed to a certain bacterial membrane. The invention includes also the use of the chemical compound sialosyllactotetraose, all the derivatives of this substance and all types of antibodies directed against them for the diagnosis of different cancer forms in different organs, and for the treatment of cancer diseases in patients.

Example 1

PREPARATION OF SIALOSYLLACTOTETRAOSE ANTIGEN IN THE FORM OF GANGLIOSIDE FROM SO-CALLED NUDE MICE AS WELL AS FROM HUMAN CANCER TISSUE.

One million viable COLO 205 cells suspended in 0,1 ml of 0,85 % NaCl. 1/15 M phosphate buffert, pH 7,2, were

0173663

inoculated subcutaneously on 4 locations on each mouse. After 4 to 5 weeks, depending on the size of the tumors grown, the animal was sacrificed and the tumors were cut away and homogenized.

5

Extraction of gangliosides from tissue

The tissue was homogenized after the addition of 3 volumes of water to one volume of tissue material. After homogenization of the tumor tissue with a knife homogenizer at 1500 rpm during 3 min., 10 volumes of methanol were added under stirring and 5 volumes of chloroform. A clear extract was isolated by centrifugation. The tissue lump 4 volumes of water were added and the tissue was homogenized again and 10 volumes of methanol and 5 volumes of chloroform were added under stirring. A clear extract was separated by centrifugation. To the combined extracts water was added to give a final chloroform-methanol-water ratio of 4:8:5.6 (by volume). After mixing in a separatory funnel, two upper phase was separated. To the lower phase there was added on equally large volume of methanol and upon mixing 0,7 volumes of water. After careful mixing the separation funnel was set aside until two distinct liquid phases were obtained. The upper phase was collected and combined with the first one. To the combined upper phases there was added isobutanol to prevent foaming, and then the extract was evaporated in a rotatory evaporator on a water bath having a temperature of 50°C. To the residue there was added 0,5 volume of methanol per volume of original tissue and 0,5 volumes of 1,0 M potassium hydroxide and was left overnight at room temperature. Then there was added 1,0 M hydrochloric acid in water to pH 8 under vigorous mixing and then against water was carried out for 48 hours.

35

The same extraction as for tumors on nude mice was carried out with human tumor tissue.

Isolation of a monosialoganglioside fraction by ion exchange chromatography

5 The dialysed crude ganglioside extract was evaporated
and redissolved in 1 ml of chloroform-methanol-water
(60:30:4.5) per gram of original tissue. A column with
an inner diameter of 20 mm was packed with Spherosil-
DEAE-dextran. (Institute Meriéux, Lyo, France) in acetate
10 form in the same solvent -at least 1 ml of ion exchanger
per each 5 g of tissue. The pure ganglioside extract was
added slowly to the column and the column was then eluted
with 10 bed volumes of chloroform-methanol-water (60:30:
4.5). The monosialoganglioside fraction was then eluted
15 with 10 bed volumes of 0,02 M potassium acetate in metha-
nol. The monosialoganglioside fraction was evaporated and
desalted by dialysis against distilled water.

Purification of sialosyllactotetraosylceramid by silica gel chromatography

20 For the chromatography 1 g of latrobeads (Latron Labora-
tories Inc., Tokyo, Japan) was used for each g of original
tissue, but at least 25 g. The gel was slurried in chloro-
form-methanol (volume ratio 4:1) and poured into a glass
25 column provided with a sintered glass filter and having
a diameter of 15-20 mm depending on the amount of gel.
The ganglioside fraction was dissolved in 10 ml of chloro-
form-methanol-water (65:25:4, by volume) and applied to
the column. It was eluted first with 15 ml of chloroform-
30 methanol-water (65:25:4) for each g (weight/volume) of
gel, which was collected in one fraction. The elution was
then continued with chloroform-methanol-2.5 M ammonia
(60:40:9, by volume) and 5 ml fractions were sampled on
a fraction collector. The elution was monitored by testing
35 10 µl of each fraction by high performance thin-layer
chromatography with the same solvents as used for the

0173663

column chromatography (HPTLC) with the same solvent as used in the column chromatography, viz, chloroform-methanol-2.5 M ammonia (60:40:9) and the gangliosides were visualized with resorcinol reagent. (Svennerholm L., Biochim. Biophys. Acta 24, 604-614, 1957). The fractions which contained sialosyllactotetraosylceramid were pooled and evaporated to dryness.

The final purification of sialosyllactotetraosylceramid was achieved by preparative thin-layer chromatography. Ganglioside (5 μ moles) was applied on a thin-layer plate (20x20 cm, 0,25 mm thick, Merck, AG., Darmstadt, West Germany), which was developed for 1 hour with chloroform-methanol-2.5 M ammonia at 21°C. After completed chromatography the plate was sprayed with 0,01% bromthymol blue in water and the sialosyllactotetraosylceramid band was scraped off. The ganglioside was eluted from the gel with chloroform-methanol-water (30:60:20, by volume) and one drop of 0,1 M potassium hydroxide dissolved in methanol was added and the mixture was evaporated to dryness. The ganglioside was dissolved in a small volume of chloroform-methanol (2:1, by volume) and was kept in a tight tube C Klimax tube with a teflon screw cap) in the dark at +4°C.

Example 2

USE OF PURIFIED SIALOSYLLACTOTETRAOSYLCERAMID GANGLIOSIDE FOR THE PRODUCTION OF MONOCLONAL ANTIBODIES DIRECTED AGAINST THE SIALOSYLLACTOTETRAOSE ANTIGEN.

The purified sialosyllactotetraosylceramid ganglioside from Example 1 was adsorbed to acid-washed Salmonella Minnesota bacteria before immunization according to the principle, described by Young, W.W. and collaborators (J. Exp. Med. 150, 1008-1019, 1979).

0173663

Balb/c mice, 6-8 weeks old, were immunized intravenously with 5 µg of ganglioside, adsorbed to 50 µg acid-washed Salmonella Minnesota bacteria suspended in 100 µl of phosphate-buffered physiological saline, pH 7.4. A new immunization was performed after two weeks with the same dose of immunogen under identical conditions (booster dose).

Three days after the booster dose, the spleen cells taken from the immunized mice were isolated and fused with mouse Sp 2/0 myeloma cells. The resulting hybridomas were expanded, tested and cloned according to the protocol devised by de St. Groth, S.F. and Scheidegger (J. Immunol. Methods, 1-21, 1980). The culture medium was collected from each microtiter well with growing hybridomas to determine whether the medium contained antibodies directed against sialosyllactotetraose. The determination was performed in an ELISA system according to the following procedure: The sialosyllactotetraosylceramide ganglioside was dissolved in methanol and 50 pmol was added to each well of a polyvinylmicrotiter plate. Upon evaporation of the methanol the wells were provided with 100 µl of hybridoma culture medium diluted with an equally large volume of 0,01 M phosphate buffered saline (0,14 M), pH 7,5. The incubation was carried out for 17 hours. Then 100 µl of peroxidase (HRP)-conjugated rabbit anti-mouse immunoglobulin diluted 1/200 in the above phosphate buffer, now provided with 1% bovine serum albumin was added to the well. The absorbance at 450 nm was determined in a Titertek microtiter scanner after incubation for 4 hours and addition of 100 µl of enzyme substrate to the well (0,1% ortophenyldiamin 1 citrate buffer, pH 4,5, mixed with 0,3% H₂O₂).

Hybrids were regarded as positive if the absorbance exceeded that of the mean medium blank by a 2-fold or

more. Culture medium from positive hybrids was collected for further screening (see below) whereas the positive hybrids were frozen in liquid nitrogen. Culture medium from hybrids positive against sialosyllactotetraosylceramide was tested against human lymphocytes for cross-reactivity. Human lymphocytes (HuLy-c) were isolated by gradient centrifugation of blood from five donors of all different ABH-blood groups and the cells were pooled. An ELISA-test on the immobilized cells was carried out. Hybrids that produced antibodies cross-reacting with HuLy-c were not further expanded. The ganglioside positive/HuLy-c negative hybrids were cloned by limited dilution and expanded. The isotype of each clone was determined by Mancinitechnique using isotype specific antimouse immunoglobulins.

The reactivity of the ganglioside positive/HuLy-c-negative clones were determined in a double antibody solid phase radioimmuno assay. The sialosyllactotetraosylceramid ganglioside and a large number of neutral glycolipids and other gangliosides were dissolved in methanol and pipetted into the wells of a microtiter plate and the methanol was evaporated. Upon incubation with the monoclonal antibodies against sialosyllactotetraosylceramid the amount of bound was detected with ^{125}I -labelled anti-mouse immunoglobulin.

The specificity of the monoclonal antibodies were also determined by thin-layer chromatographic immunostaining of the ganglioside antigens. The total ganglioside fraction isolated from a number of different tumor tissues were separated on alumina-backed high performance thin-layer plates (HPTLC) and incubated with the culture medium from the positive hybridomas, diluted with Tris buffered saline (pH 7,8) containing 1% bovine serum albumin. Bound monoclonal antibody was detected with ^{125}I -labelled

antimouse immunoglobulin which was exposed to X-ray film for 12-24 h.

5 The monoclonal antibodies examined have all reacted negatively against neutral glycolipids. The major part of the antibodies having been positive against the sialosyllactotetraosylceramid ganglioside have shown a vigorous reaction with gangliosides having the same carbohydrate structure but also containing fucose linked to
10 N-acetylglucoseamine.

Example 3

DETERMINATION OF SIALOSYLLACTOTETRAOSE ANTIGEN I TUMOR TISSUED

15

The tumor antigen has been isolated both as a glycolipid as well as a glycoprotein. When the antigen has been isolated as a ganglioside, the same principle method was used as described in Example 2, but the method has been adapted to small tissue samples used for analysis.

20

Detection of the ganglioside antigen

25

0,5 ml of water was added to about 0,1 g of tissue and the tissue was homogenized in a conical homogenizer with teflon pestle in an ice bath. After finished homogenization 1.6 ml of methanol and 0.8 ml of chloroform were added. After thorough mixing the tube was centrifuged at 100xg for 10 min. The clear supernatant was transferred to a small Kimax-tube with teflon cap. The sediment in the tube was suspended in 0.5 ml of water and then
30 methanol and chloroform were added in the same volumes as used in the first extraction. Mixing and centrifugation were performed as before. The two supernatants were combined and water was added to give a final chloroform-methanol-water ratio 4:8:5.6 (by volume). Centrifugation
35 was performed at 100xg for 5 min. The upper phase was transferred to a small round flask with ground neck and

0173663

0.5 ml chloroform and 1.0 ml water were added to the lower phase. Upon mixing 0.7 ml water was added and after renewed mixing centrifugation was performed at 100xG for 5 min. The upper phase was transferred to the round flask with ground neck and 0,1 volume of iso butanol added. The residue was evaporated to dryness with 0.1 M NaOH in methanol. The tube was left for 1 h at room temperature.

After finished transesterification 4 ml of chloroform and 1 ml of methanol were added and the content was poured into a small column with 1 g of Sephadex G 25, packed in chloroform-methanol-water (60:30:4.5 by volume). The column was eluated with 15 ml chloroform-methanol-water (60:30:4.5). The eluate was slowly added to a column packed with 1.0 g of DEAE-Sepharose[®] (Pharmacia Fine Chemicals, Uppsala, Sweden) in acetate form. After rinsing the column with 10 ml of methanol, the monosialogangliosides were eluted with 10 ml of 0,02 M potassium acetate in methanol. After evaporation and redissolution in chloroform-methanol-water (65:25:4 by volume) the simple monosialogangliosides were separated from sialosyllactotetraosylceramid by elution with 15 column volumes of 65:25:4 (weight/volume), whereafter the complex ganglioside fraction was eluted with 10 volumes of chloroform-methanol-water (50:40:10 by volume).

An aliquot of the purified complex ganglioside fraction of tissue was dissolved in methanol and 50 µl of extract was added to one of the wells of a polyvinyl microtiter plate. Standard solutions of 1 to 25 pmol of pure sialosyllactotetraosylceramid in methanol were added to the other wells of the plate. The solvent was evaporated under a stream of nitrogen. To the unknown samples and standards there were added 10-100 µg of monoclonal antibody, specific for sialosyllactotetraose with fucose, if any, linked

0173663

to said molecule, and produced as described i Example 2,
dissolved in phosphat-buffered physiological saline,
pH 7.4, as well as 1% bovine serum albumin (PBS). The
5 samples were incubated for 1 h at room temperature, and
then the well was washed 3 times with PBS solution. Then
125I-labelled antimouse-immunoglobulin was added and
allowed to react for 3 hours. After repeated washing
with PBS the wells with unknowns and standards were cut
10 out from the microtiter plate and counted in a gamma
counter. The concentration of sialosyllactotetraose anti-
gen of the unknowns were calculated from the standard curve
of pure sialosyllactotetraosylceramid.

The protein-linked form of the sialosyllactotetraose
15 antigen was detected by means of immunological isotope
and enzyme methods. 100 µl of the aqueous homogenate of
tumor tissue were added to an incubation tube and then
100 µl of monoclonal antibody were added and mixing was
carried out. The tube was sealed and incubated for 90 min.
20 at room temperature and under slow shaking. To each tube
there was added a polystyrene bead on which a thin layer
of the sialosyllactotetraosylceramide ganglioside antigen
had been applied. After the addition of the antigen bead
the tube was tapped slightly in order to remove any air
25 bubbles present on the plastic bead. Then the sample was
incubated for 4 hours. The incubation solution was sucked
off with a water aspirator and the beads were washed with
2x2 ml of phosphate-buffered physiological saline. The
washing liquid was removed as careful as possible. Then
30 200 µl of ¹²⁵I-labelled antimouse antibody were added and
incubation was performed during the night at +4°C. The
antibody solution was sucked off and the beads were washed
with 4x2 ml of phosphate-buffered physiological saline.
The washing liquid was removed carefully between each
35 washing. The incubation tube with bead was placed in a
gamma counter and the number of cpm of ¹²⁵I was determined.

0173663

At each analysis a blank (free from antigen) was analysed. Further, at least one positive sample (an aqueous extract from a tumor with known occurrence of antigen) was always analysed. The inhibition was determined and from the
5 first value it has been possible to make dilutions of the tumor extract in case the inhibition has been too big. The sialosyllactotetraose inhibition test gave a high frequency of positivity in different forms of tumor varying between 35-80%. A certain activity of the water-
10 soluble antigen was found in certain organs, such as the small intestine, the large intestine and pancreas. The sialosyllactotetraose antigen test in lipid extract (as ganglioside) gave, as a rule, higher specificity (no positive tests in normal tissue) as well as a larger
15 number of positive tests on tumor tissue. In the present case the detection step is based upon an isotope-labelled second antibody in the immunological inhibition test.

Example 4

20 DETERMINATION OF SIALOSYLLACTOTETRAOSE ANTIGEN IN BLOOD SERUM FROM PATIENTS HAVING CARCINOMA

100 μ l of patient serum were added to an incubation tube and then 100 μ l of the monoclonal antibody were added, and
25 mixing was performed. The tube was capped and incubated for 90 min. at room temperature under slow shaking. Then there was added to each tube a polystyrene bead coated with sialosyllactotetraosylceramid. Any air bubbles present were allowed to disappear by careful tapping of
30 the tube. The incubation was performed for additional 4 hours. After said time the incubation solution was sucked off with a water aspirator and the beads were washed twice with 2 ml of phosphate-buffered physiological saline. The washing liquid was removed as careful as
35 possible. Then 200 μ l of 125 I-antimouse antibody were added and incubated over the night at +4°C. After said

0173663

time the antibody solution was sucked off and the beads were washed four times with 2 ml of phosphate-buffered physiological saline. The washing liquid was removed carefully between each washing. The incubation tube with its polystyrenebead was counted in a gamma counter and the number of counts was determined.

Example 5

10 DETERMINATION OF SIALOSYLLACTOTETRAOSYLCERAMID IN BLOOD
SERUM FROM PATIENTS WITH CARCINOMA

15 1 ml of blood serum diluted with 0,5 ml of physiological saline was added dropwise to 4 ml of methanol in a small Kimax tube under continuous mixing. Then 2 ml of chloroform were added and the sample was thoroughly mixed and centrifugated at 800xG for 10 min. The clear centrifugate was transferred to a small round flask and was evaporated to dryness. It was dissolved in 5 ml of chloroform and was applied on 1 g silica gel column (Kieselgel 60, 20 230-400 mesh, Merck AG, Darmstadt, West Germany). The column was eluated with 10 ml of chloroform and 15 ml of chloroform-methanol-water (65:25:4, by volume) and then the ganglioside antigen was eluated with 10 ml of chloroform-methanol-water (50:40:10). The last eluate 25 was added slowly to a column of 1 g DEAE-Sepharose, which then was eluated with 10 ml of methanol. Complex monosialogangliosides were the eluated with 10 ml of 0,02 M potassium acetate in methanol. The salt was removed by dialysis against distilled water and the ganglioside 30 fraction was dissolved in methanol.

35 The concentration of sialosyllactotetraosylceramid was determined with a double solid phase antibody method, in which the ganglioside was adsorbed to the solid phase and determined with monoclonal antibody and antimouse-immunoglobulin. 20 pmol of pure sialosyllactotetraosylceramid

0173663

and samples of pure monosialoganglioside fraction from serum were dissolved in methanol and serial dilutions of them (1/2-1/2048) were pipetted in the wells of polyvinyl microtiter plates (Flow Laboratories art.nr. 77-173-05) and were evaporated. The wells were blocked with 20 μ l of 1% bovine serum albumin (BSA) in phosphate-buffered physiological saline (PBS) and then 50 μ l of monoclonal antibody against the antigen, diluted in 1% BSA in PBS, were added. After incubation for 4 hours, the wells were rinsed with 3x200 μ l of PBS.

After the rinsing fixed monoclonal antibody was measured by addition of antimouse immunoglobulin labelled with ^{125}I or with peroxidase or β -galactosidase. Measurement of the concentration of the other antibody was performed in a gamma counter or after addition of enzyme substrate (ortophenyl diamin or methylumbelliferyl- β -galactoside in citrate buffer, pH 4.2, and reading of the fluorescence in a spectrofluorimeter after 30 min). The concentration of sialosyllactotetraosylceramid was calculated from standard samples of the purified ganglioside. Under the conditions specified above, antigen serum was only detected in patients with adenocarcinoma.

CLAIMS

1. The use of a specific tumor associated antigen/hapten of carbohydrate nature, sialosyllactotetraose ($\text{IV}^3\text{NeuAC LcOse}_4$) for diagnostic and therapeutical procedures related to human tumor diseases.
- 5 2. The use of claim 1, wherein antibodies or other reagents directed against the antigen are used for detection, determination, localization and treatment.
- 10 3. The use of claim 1, wherein the antigen is isolated in the form of a sialosyllactotetraosylceramid from carcinoma or its metastases.
- 15 4. The use of claim 1, wherein the antigen or its derivatives in immunogenic form are used for the production of antibodies directed against the antigen which antibodies are monoclonal or polyclonal.
- 20 5. The use of claim 1, wherein bound specific monoclonal antibody is determined by means of enzymes, e.g. β -galactosidase or peroxidase, radioactive isotope, e.g. ^{125}I , or a fluorochrome, e.g. dansyl chloride.
- 25 6. The use of claim 1, wherein the determination of antigen is effected on cellular level in histological preparations or tissue sections by means of immunohistochemical methods.
- 30 7. The use of claim 1, wherein tumor and tumor metastases in patients are localized by means of antibodies labelled with radioactive isotope or labelled by other means.
- 35 8. The use of claim 1, wherein antibodies against sialosyllactotetraose are used in the treatment of carcinoma.
